

CREDIT RISK ANALYSIS

ABSTRACT

Understand which are the key factors for a certain level of credit risk to occur

Compare the performance of different ML models capable to predict the credit risk level for a company in an year - given past years data

Keywords

ML MODELS

Credit risk level prediction and models comparison

01♣ INTRODUCTION

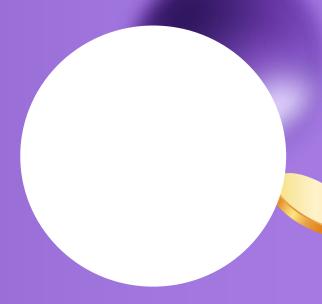

WHAT IS CREDIT RISK ANALYSIS

Credit analysis is a type of financial analysis that an investor performs on companies to measure the issuer's ability to meet its debt obligations (calculated using financial ratios, cash flow analysis, trend analysis, and financial projections)

Credit analysis seeks to identify the appropriate level of default risk associated with investing in that particular entity's debt instruments

A review of credit scores and any collateral is also used to calculate the creditworthiness of a business

DATASETS

The main dataset contains the following features (from 2015 to 2020), regarding European companies:

- Name: name of the company
- Turnover: how quickly a company collects cash from accounts receivable or how fast the company sells its inventory
- EBIT: indicator of a company's profitability
- PLTax: company tax based on their cumulative income over their lifetime up until the filing date
- MScore: The higher the M-score level of a company, the more likely the company engages in accounting frauds
- Country: worldwide country of the company

DATASETS

- NACE code: European statistical classification of economic activities
- Sector 1: detailed description of the company's business activities
- Sector 2: general sector
- Leverage: the use of debt to amplify returns from an investment or project
- ROE: measure of a company's annual return
- TAsset: assets owned by the company

Other accessories datasets have been downloaded from <u>Kaggle</u> to extract other useful information, to gain more effective insights

YEARS

Is it possible that after a company gets D credit risk level in an year, the consequent one still gets a D?

```
test_df = companies_df[companies_df['MScore.'+str(year_widget.value)] == companies_df['MScore.'+str(year_widget.value+1)]]
n = test_df[test_df['MScore.'+str(year_widget.value)] == 'D'].count()[0]
```

153 companies had a D credit risk level in 2019 and the consequent year

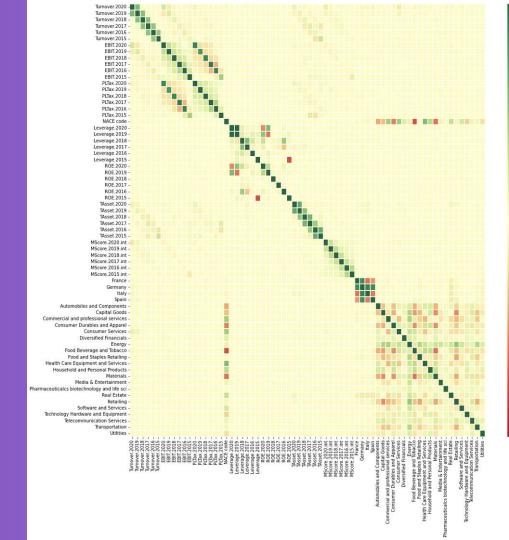

Did Covid-19 led an increase in the number of high credit risk companies?

Percentage increase in high risk level companies in 2020 (with respect to previous years): 32.6%

Correlation is not causation!

PARTIAL CORRELATIONS

- 0.50

- 0.25

O4 ML MODELS

UNBALANCED CLASSES

Average number of low level credit risk companies: 107824 Average number of high level credit risk companies: 13184

```
# Fix the unbalanced case
high_risk_df = companies_df[companies_df['MScore.2019.int'] == 1]
low_risk_df = companies_df[companies_df['MScore.2019.int'] == 0].sample(n=len(high_risk_df), random_state=0)
restricted_df = pd.concat([low_risk_df, high_risk_df])
restricted_df.sort_index(inplace=True)
```

Beware of the year choice, because of the already mentioned Covid-19 effect Objective: predict 2019 credit risk level (selection through slider)

FEATURE SELECTION

Start considering a very easy model (LogReg)
Whether features values are ranging not in [0, 1], MinMax scaling has been applied

Easiest model: credit risk level of previous year, to predict the one of next year

```
X = restricted_df[['MScore.'+str(year_widget.value)+'.int']]
y = restricted_df[['MScore.'+str(year_widget.value + 1)+'.int']]
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0, test_size(0.2), shuffle=True, stratify=y)
      MScore.2018.int
                                                           lr = LogisticRegression(solver='liblinear', random_state=0)
                                                           lr.fit(X train, np.ravel(y train))

FEATURE SELECTION

The overall obtained performances can be considered good, but what if we add other features?

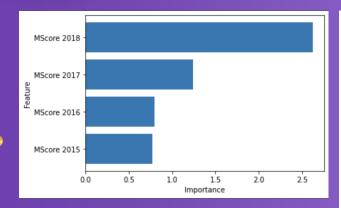

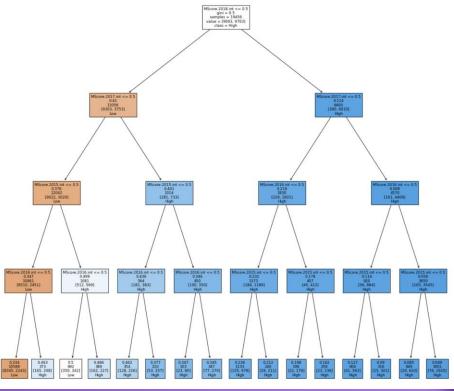

Adding other previous year data like EBIT, Leverage, Turnover, PLTax, ROE, and/or constant features (general sector, country), singularly does not significantly improve the performance metrics. Whereas, combining all of them together it changes, but not so much to justify the loss of interpretability

Add more than one year old data, like all past years credit risk level scores allows to improve significantly the performance metrics (5% of test accuracy increase). Instead, adding other more than one year old data (EBIT, Leverage, ROE, Turnover, ...) does not improve so much the performance metrics

Same occurs when predicting other years credit risk levels (features weights and performances metrics change due to variable in time dynamics)

FEATURE IMPORTANCE AND DECISION TREE

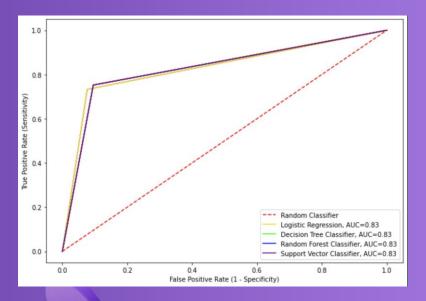

MODEL COMPARISON

What happens to performances metrics if we consider other more complex ML models?

THANKS!
